Literature Review Paragraph

[Main Point] In contemporary literature, cybersecurity on social media platforms such as Facebook, Instagram, TikTok, X (Twitter), and Telegram is widely recognized as a critical issue affecting users' privacy, data security, and online behavior.

[Synthesis] Researchers such as Gupta and Sharma (2023) and Alharbi (2024) agree that social media platforms have become major targets for cyber threats, including phishing attacks, identity theft, and data breaches. Gupta and Sharma (2023) argue that the rapid growth of social networking services has increased opportunities for cybercriminals to exploit users' personal information. Similarly, Alharbi (2024) found that weak privacy settings and low cybersecurity awareness among users significantly contribute to online security incidents.

[Analysis] These findings suggest that cybersecurity risks on social media are not solely technological problems but also behavioral issues. As social media usage increases, users' knowledge and security practices become essential factors in preventing cyberattacks. Effective cybersecurity therefore requires both advanced security mechanisms and improved digital literacy among users.

[Evaluation] However, not all scholars share this perspective. Nguyen (2023) argues that the built-in security systems of major social media platforms are generally sufficient and that cyber incidents mainly result from individual negligence rather than weaknesses in the platforms themselves. This contrasting view indicates that further research is needed to determine the relative influence of platform security measures and user behavior in mitigating cyber risks.
